TITLE: Early post-irradiation reactions and their modification by means of  
chemicals  
*(vol. 1)*

SOURCE: Kosmos--Seriya A (Biologia), no. 1, 1964, 23-31

TOPIC TAGS: primary irradiation reaction, irradiation reaction mechanism,  
irradiation prophylaxis, chemical prevention mechanism, free sulphydryl radical

ABSTRACT: Review article. Effect of ionizing radiation on living organism is due not to energy imparted by radiation but to physical and chemical changes due to it. Neither the original target theory nor the theory of indirect effect has fully explained the mechanism of occurring biological reactions or the modifying effect of preventively administered chemicals. Studies heretofore have established a priority of biochemical effects, which include changes in the activity and coordination of enzymes, enzymatic degradation of macromolecules and formation of atypical toxic substances in the cell, disorders in protein and DNA synthesis, blocking of oxidative phosphorylation (especially in cell nuclei),

Card 1/81

ACCESSION NR: AP4013649

and inactivation of free SH groups there. It is not yet clear, however, if these are the only primary effects, whether they are interdependent, and which are responsible for later effects.

Radiological chemistry research has disclosed many substances which can alleviate the effects of radiation, but relatively few which can prevent them. These include lower-chain members of the cysteamine group (free SH and NH<sub>2</sub> radicals) some sulphydryl isothiourea derivatives (free SH and guanadine), colloidal sulphur and some sulphur-containing organic compounds, as well as some pharmacological agents which inhibit metabolism, affect the central nervous system, or cause methemoglobinemia. However, even with the most effective agents (cysteamine, AET, serotonin, and some mixtures) the best result obtained was survival of animals of a 2-3 times medium lethal dose, and in vivo checks of the mechanism have not been established. The mechanism may involve the inactivation of the radiolysis products, direct combination with cell or protein components (sulphydryl to bisulphide), or reduction of oxygen to block the harmful radiation reaction. Clarification of mechanisms and successful protection must, however, await further advances in life sciences. Orig. art. has:8 formulas.

TITLE: Biochemical lesions induced in subcellular structures by ionizing radiation.  
III. Cytochrome c oxidase and glucose-6-phosphatase activity of rat liver

19

SOURCE: Nukleonika, v. 10, no. 12, 1965, 783-789

TOPIC TWS: ionizing radiation, enzyme, radiation biologic effect, rat, liver

ABSTRACT: Cytochrome c oxidase and glucose-6-phosphatase activity of subcellular fractions isolated from rat liver were assayed at 0.2 or 24 hours after whole-body irradiation of rats with a dose of 750 R. No definite changes in activity of cytochrome oxidase were found, whereas an increase in glucose-6-phosphatase activity in nuclear (at 0, 2 and 24 hr) mitochondrial (at 2 and 24 hr) and in microsomal (at 2 hr) fractions were clearly demonstrated. The authors thank Professor Edward Kowalski for his interest and critical discussion during this work. Expert technical assistance was provided by Mrs. Dobrosława Rzeppińska and Mr. Leszek Turkiewicz.

TITLE: Biochemical lesions induced in subcellular structures by ionizing radiation.  
II. Catalase activity in rat liver and spleen

SOURCE: Nukleonika, v. 10, no. 9-10, 1965. 553-557

TOPIC TAGS: biochemistry, ionizing radiation, enzyme, rat, liver, radiation biologic

ABSTRACT: The catalase activity of subcellular fractions isolated from rat liver and spleen were determined at 0, 2, or 24 hr after whole-body irradiation of rats with a dose of 750 r. A decrease in enzyme activity was found in whole homogenate and cell sap fraction of the liver at 24 hr after exposure. In spleen the decrease in catalase activity was observed in particulate fractions at 0, 2, and 24 hr after exposure. This decrease was accompanied with an increase in the catalase activity of the cell sap fraction of the spleen. The author thanks Professor E. Kowalski for his interest in this work; Mrs. Dobroslawa Rzepniewska and Mr. Leszek Turdewicz for their valuable technical assistance; and Misc Barbara Panfil, M. Title : Determination of Lithium, Sodium, Potassium, and  
Calcium in Perhydrol by the Method of Flame Spectroscopy.

Orig Pub : Chem. analit., 1958, 3, No 5-6, 729-736

Abstract : A method was developed for the determination of lithium,  
sodium, potassium, and calcium in perhydrol for concent-  
rations (in percent):  $6 \times 10^{-4}$  for lithium,  $2 \times 10^{-2}$   
for sodium,  $10^{-2}$  for potassium, and  $2 \times 10^{-2}$  for calcium.  
The burner of a Zeiss flame photometer was used. The  
analytical lines were (in Angstroms: lithium 6708, sodium  
5890 and 5896, potassium 7665 and 7699, calcium 4226.

AUTHORS: Mazov, A. V. Turskiy, Yu. I. and Danchenko, L. Ye.

TITLE: Separation of Phenols from Tar Fractions with Aqueous Solutions of Methanol (Izvlecheniye fenolov iz smolyanykh fraktsiy vodnymi rastvorami metanola)

PERIODICAL: Khimiya i Tekhnologiya Topliv i Masel, 1958, <sup>3</sup> Nr 10,  
pp 44 - 49 (USSR)

ABSTRACT: Separation of phenols is at present carried out with the aid of selective solvents. The authors give a brief review of the use of selective solvents since 1903 (Refs. 1 - 9). In 1954 pilot plant experiments were made on the separation of phenols with methanol; the lay-out of the pilot plant is shown in a Figure. The fraction was diluted with petroleum ether and the extraction carried out on a 75 mm diameter and 7.8 m high column, two sections of which were filled with 8 x 8 mm Raschig rings. The mixture of the fraction with petroleum ether was led into the lower part of the column through a jet with a 2 to 2.5 mm diameter nozzle. The following fractions were tested: the fraction 160 to 210°C and 210 to 320°C obtained during the semi-coking of Cherkessk coal; the 150 to 260°C fraction of tar obtained

Card 1/4

SOV/65-58-10-1C/15  
Separation of Phenols from Tar Fractions with Aqueous Solutions of  
Methanol

during the gasification of brown coal; the fraction 190 to 300°C of tar obtained during the processing of peat. Characteristics of these fractions are given in Table 1. Optimal conditions for the separation of phenols from various types of raw material are shown in Table 2. Continuous work on the column could be carried out for 10 to 30 days. A considerable part of the neutral compounds is separated from the methanol extract by washing the same with petroleum ether in a separate extraction column. Table 3: the content of neutral compounds in extracts separated with methanol from various tar fractions before and after washing with petroleum ether. These neutral substances consisted of more than 90% of oxygen-containing compounds, the composition of which was determined by chromatography. 92.5% phenols and about 0.4% hydrocarbons were separated from the 210 to 320°C fraction. Practically complete separation of the asphaltenes was achieved. Most of the organic bases contained in the fractions passed into the methanol extract. 43% of organic bases were separated with methanol from the

Card 2/4

SOV/65-58-10-10/15

Separation of Phenols from Tar Fractions with Aqueous Solutions of Methanol

160 to 210°C fraction of the middle oil obtained during the semi-cooking of Charemkiyvsk coal, and 22% of organic bases from the 210 to 320°C fraction of the same oil. The experiment also proved that the residual content of phenols in the raffinate can be decreased to 0.9 - 1.2%. Part of the water remained in the extract and the moisture content of crude phenols was 12 to 16%. Yields and properties of the phenols are given in Table 4. Results obtained during the separation of phenols by the distillation of low-boiling fractions (Table 5) can be considered satisfactory. The neutral compounds are concentrated in the high-boiling fractions and the residue, therefore, contains high-quality fractions. The xylene fraction, which contains the highest quantity of neutral compounds, can be used

AUTHORS: Naftulovich, S. M.; Danchenko, N. F.

TITLE: Cast-iron rolls replace steel rolls

PERIODICAL: Metallurg, no. 8, 1961, 26

TEXT. The bottom and middle steel rolls in the three-high plate mill (Lauth type) at the Metallurgical Plant imeni Petrovskiy have been replaced by chilled cast-iron rolls of 893 mm in diameter. The rolls have chilled layers 15 - 20 mm and 20 - 22 mm thick, respectively with a Shore hardness of 60. The composition of the middle roll is 3.06% C, 0.32% Mn, .40% Si, .08% S, 0.54% P, 0.07% Cr and 0.30% Ni. Corresponding percentages for the bottom roll are: 3.07, 0.35, 0.46, 0.08, 0.55, 0.06, 0.34. The advantages of the rolls are: the amount of rolled plates until normal wear of the rolls is raised by a factor of 2.5; the use of the rolls until regrinding is raised by a factor of 1.5; the wear of the middle and bottom roll is approximately equal, so that the rolling process is more stable. The rolls worked for 17 shifts without being changed and rolled 6,493 tons (middle roll) and 5,900 tons (bottom roll) for one mm of wear. Roll

Title : Use of Sodium Alginate to Ameliorate the Technology of Concrete Mixes

Orig Pub: Dokl. Bolg. AN, 1957, 10, No 2, 117-119

**Abstract:** Na-alginate improves the structure of concrete, increases its plasticity and density, promotes enhanced impermeability to water, resistance to frost and chemical stability. Na-alginate added in an amount of 0.01-0.05% of the weight of cement, increases compression strength at the age of 28 days up to 8%. Concrete with added Na alginate does not undergo stratification on jarring.

NiMn<sub>2</sub>O<sub>4</sub> has been established for the mixture I and for the two oxide systems. The intermediary mixtures, II to V included, are represented by cubic spinels of a variable cation composition. Mixture VII is represented by the tetragonal spinels CoMn<sub>2</sub>O<sub>4</sub> and ZnMnO<sub>2</sub>. On the basis of data from the literature on the position of the metal cations in NiMn<sub>2</sub>O<sub>4</sub> and CoMnO<sub>4</sub> an attempt has been made to elucidate the distribution of the cations in the spinel structures of thermistors studied by the authors. Orig. art. has: 3 figures and 2 tables. [Based on author's abstract]

TITLE: Some properties of thermistors made of three-compound oxide systems

SOURCE: Bulgarska akademiya na naukite. Doklady, v. 18, no. 6, 1965, 525-528

TOPIC TAGS: thermistor, semiconductor research, admixture, x-ray analysis

ABSTRACT: Thermistors are usually made of oxide mixtures (see, e.g., N. P. Potapov, Tr. Odessk. hidro-meteorol. i-ta, 37, 1956, No. 8; N. Ya. Kushnarev, V. P. Linde, S. Z. Roginskiy, FTT, III, 1961, No. 2, 384). The present paper describes the production of three-component  $MnO_2-Ni_2O_3-OO_2-O_3$  and  $MnO_2-Ni_2O_3-ZnO$  systems whose properties may be altered by small admixture activation. In addition to the Volt-Ampere and temperature characteristics of the system, the authors present also comprehensive results of X-ray structural analysis of the various semiconductors produced and the distribution of metallic admixtures within the spinel structures. This paper was presented by Academician G. Nadjakov on 23 February 1965. Orig. art. has: 2 figures and 2 tables. [Orig. art. in German] [JPRS]

TITLE: Influence of impurities on the semiconductor properties of thermistors composed of  $MnO_2$ - $Co_2O_3$ - $Ni_2O_3$

SOURCE: Bulgarska akademiya na naukite. Fizicheski institut. Izvestiya na Fizicheskiya institut s ANEB, v. 13, no. 1, 1965, 193-200

TOPIC TAGS: thermistor, electric property, resistor, semiconductivity

ABSTRACT: Heat-sensitive resistors with a negative temperature coefficient are obtained from metal oxides in a ratio of  $MnO_2$ -60%,  $Co_2O_3$ -29.7% and  $Ni_2O_3$ -1.3%. The oxide mixture is doped with solutions of  $Li_2CO_3$ ,  $Cu(NO_3)_2$ ,  $CsCl$ ,  $CeCl_3$ ,  $Ce(SO_4)_2$  compounds of concentrations of the order of  $10^{-6}$ ,  $10^{-5}$ ,  $10^{-4}$ ,  $10^{-3}$ ,  $10^{-2}$ ,  $10^{-1}$ ,  $10^0$  wt % of the metal activator. The obtained mixture is wet-milled

Z

Card 1/2

L 23316-66

dried at 80C and then dry-milled again. The electrical properties of the thermistors obtained by pressing, sintering at 1150C and again at 120C for 200 hours are investigated. By increasing the concentration of the activator the resistance  $R_{20}$  of the samples activated by  $\text{Li}^+$  and  $\text{Cu}^{2+}$  decrease from the order of 1 to 3.5, while the  $R_{20}$  of those activated with  $\text{Ca}^{1+}$ ,  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  showed no significant changes. The thermistors have a temperature coefficient  $\alpha_{20}$ . The X-ray investigation indicated a new phase in the form of tetragonal spinel  $\text{CoMn}_2\text{O}_4$ . No structural changes were produced by small amounts of activators. Orig. art. has 2 figures and 4 tables. [Based on author's abstract]

TITLE: On the Relationship Between the Initial Pressure of an Explosion and the Charge Coefficient (O zavisimosti nachal'nogo davleniya vzryva ot koefitsiyenta zaryazhaniya)

PERIODICAL: Tr. In-ta geol. AN KirgSSR, 1956, Nr 7, pp 105-110

ABSTRACT: The paper adduces the calculations of the maximum pressures of explosive gases in a blast hole and the specific power delivered by an explosion in relation to the ratio of the charge diameter to the diameter of the blast hole. The dynamic nature of the process of detonation is not taken into consideration, and it is assumed that the explosive gases in their initial state obey the formula usually applied to internal ballistics with the covolume taken into account

Method of study of the color of sedimentary rocks. V. I.  
Danchev (Inst. Geol. Ore Deposits, Petrography, Mineral.,  
and Geochem., Acad. Sci. U.S.S.R., Moscow). Issled.  
Akad. Nauk S.S.R., Ser. Geol. 1956, No. 7, 49-60.—  
Brief survey and crit. evaluation of methods of study of  
color of sedimentary rocks. The photometric method is  
suggested for obtaining quant. characteristics of color.  
A brief discussion of the photometer and methods of its use  
are given. Attention is called to the relation of color of  
sedimentary rocks to their material compn., and to the  
feasibility of using color for genetic and prospecting pur-  
poses. 26 references.

TITLE: The Significance of the Quantitative Determination of the Color of Rocks in the Study of the Sedimentary Deposits of Uranium Ores (Znachenije kolichestvennogo opredelenija tsvetov porod pri izuchenii osadochnykh mestorozhdeniy uranovykh rud)

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geologicheskaya, 1958, Nr 11, pp 71 - 83 (USSR)

ABSTRACT: This article deals with photometric method of determining the coloration of uranium-bearing carbonaceous rocks. The author analyzes the connection between rock coloration and its contents of uranium compounds, organic substances and various forms of iron. L.W. Patnode, F.D. Trask and other U.S. scientists are cited by the author, who describes their method of detecting uranium according to the coloration of various sedimentary rocks. There are 6 graphs, 4 diagrams and 24 references, 15 of which are Soviet, 8 American and 1 English.

TITLE: Certain Problems of the Genesis of Uranium Mineralization in Connection With the Study of Effective Porosity of Ore-Containing Carbonaceous Rocks

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya Biologicheskaya, 1959, Nr 7, pp 16-25 (USSR)

ABSTRACT: According to the prevailing opinion, the carbonaceous sedimentary strata, containing uranium ore, were formed as a result of favorable continental-maritime conditions at the time of their sedimentation. Following intensive rock erosion, the uranium-bearing compounds were washed down in the coastal maritime areas. Regeneration conditions, caused by the accumulation of organic substances, aided in the sedimentation of uranium compounds from muddy waters, with the ensuing sorption of these compounds by organic and colloidal parts of the sediment. Minerals thus formed were again redistri-

buted during the diagenetic and epigenetic processes. This is also the authors' opinion. Some geologists thought that uranium deposits were formed as a result of either a hydro-thermal-metasomatic process or of a metamorphic action of thermal solutions. In both cases this action was rendered possible by a greater effective porosity of ore-bearing rocks than that of oreless ones. The author checked the degree of porosity of ore-bearing rocks by a slightly modified method elaborated by I.A.Preobrazhenskiy. It consists of soaking (in water) the samples of rocks previously dried out in a vacuum. The difference in weight of a sample gives an idea of the volume of pores of the said sample and the relation between the volume of pores and that of rocks gives the factor of effective porosity (PEF). Samples were taken from the most wide-

ly spread varieties of ore-bearing rocks such as: 1) limestones of oolithic structure; 2) limestones of organogenic structure and 3) dolomites and calcareous dolomites of crystalline structure. Altogether, 252 tests were made. The results showed that samples of the first two groups have a much lower effective porosity factor (4.3% and 5.2%) than those of the third group (10.2%). Thus, dolomites and calcareous dolomites of crystalline structure have the highest porosity factor and at the same time contain only small quantities of uranium ores. The correlation between uranium content and the effective porosity of rocks is shown in figure 3. The lower part of this graph covers samples of variegated rocks of all three of the above mentioned groups with poor but evenly distributed ore concentration and with a high effective

porosity factor. Samples of rocks with a higher ore content, and the lowest effective porosity factor, are covered in the medium part of the graph. An even distribution of uranium ore is the main characteristic of this group of samples, belonging to the limestones of orogenic structure and forming the main group of ore-bearing rocks. The upper part of the graph covers limestones of eolithic structure with the highest ore content but with a very variable (from 1% to 8-9%) effective porosity factor. Such variations depend, according to the authors, on genetic features of sedimentary uranium ore deposits associated with the carbonaceous rocks. For instance the simultaneous increase of the porosity and of the ore content is connected with the stage of their epigenetic transformation which occurred during the

elevation process causing the erosion of these elevated rocks, that is increasing their porosity without carrying away the uranium bearing minerals. Extensive radiographic study of the distribution of uranium (figures 4,5,6) in different parts of ore deposits shows that dispersive forms of mineralization prevail in those parts of deposits which were less subject to the recrystallization and lixiviation processes. This, say the authors, confirms the theory of the primarily-sedimented genesis of mineralization. In rich ores, with a higher effective porosity factor, the prevailing veined mineralization is a result of a process of epigenetic migration of mineral ore-components. The following geologists are mentioned by the authors: V.V. Veber, I.I. Romm, V.G. Savich, N.M. Strakhov, L.B. Rukhin and L.V. Purtovnikov. There are
